DLC--Most important problems of industrial hygiene in modern farming are: 1) protection of human organism from unfavorable meteorological conditions (high and low temperatures, extreme insolation, high humidity) and 2) protection from dust and gases. Investigations of Kiev Institute show that tractor drivers and other operators of farm machinery have somewhat higher body temperature as a result of high air temperatures and high insolation. Kiev Institute constructed special umbrella and driver's cabin (double-walled with thermo-insulating floors and front wall) to protect the driver from radiation effects. *Subject Headings*: 1. Physiological climatology 2. Heat effects on man 3. Industrial hygiene.--S.A.

The article reviews the scientific reports presented at the Hygiene Section of the All-Union Conference on Medical Radiology (30 January to 4 February 1956, Moscow).

Among the topics embraced are the following: radiation hygiene and dosimetry; hygienic standardization and the establishment of maximum permissible levels of external irradiation and maximum permissible concentration of radioactive substances in the atmosphere and water; hygienic characteristics of industries and laboratories using radioactive substances; basic factors in the injurious action of radioactive substances and methods for improving working conditions where they are used; sanitary-hygienic and technical requirements in the planning and equipment of laboratories using large amounts of radioactive substances; the cleansing of hands contaminated with radioactive substances; determination of alpha-active aerosols in the air; individual protection of workers; selection of polymer materials and resin for use in individual protection; resins for individual protective clothing which can be washed free of radioactive substances; description of a new type of valveless respirator, the "Lepestok," for once-only use; cleansing of individual protective clothing items of cotton and plastic; disposal of radioactive wastes; and the behavior of radionuclides in water under experimental conditions. LETAVET, A. A.

"Problems of Hygiene in Radiology," by Prof A. A. Letavet, Medit-sinskaya Radiologiya, Vol 2, No 1, Jan/Feb 1957, pp 11-22

The article discusses problems of hygiene and sanitation arising as a result of the use of atomic energy and radioactive substances in the USSR, from the standpoint both of workers in the atomic energy industry and of the population in general. Solutions for these various problems are proposed.

An important problem in assuring safe working conditions in laboratories where exposed radioactive substances of significant activity are used is the proper planning of the buildings and work to assure "radiological cleanliness" of the area. The work should be conducted in special sealed boxes through protective gloves passing through the walls of the box or by means of various manipulators. "Dirty" work should be done in special protective costumes and with the use of other means of protection.

Ventilators are important in providing for the necessary purity of the air.

Summary 1345

LETAVET, A.A.

It is understood that in providing for safe conditions of work at various production plants and in laboratories using radioactive substances, an important role is played by proper design of protection from external gamma and neutron irradiation. An important question of prophylaxis which is common for all branches in the use of uncovered radioactive substances is the problem of individual protective measures, especially protective dress and respirators for protecting the organs of respiration. The requirements for protective clothing and other protective devices consist of the following: complete protection of the organism and easy cleansing of radioactive contamination.

In the search for satisfactory materials meeting these requirements for protective clothing one must consider certain hygienic qualities of clothing (its air- and moisture permeability) and use various types of plastic materials -- polymer films. It is possible, however, to take another direction, that is, the preparation of certain articles of dress, shoes, and respirators from cheap, discardable materials to be used only once and then to be destroyed.

For work under conditions when, for one reason or another dangerous contamination of the surrounding air has taken place, the use of protective pneumocostumes with forced air feed (LG-1, LG-2) can be recommended. To provide the worker with normal heat transfer by evaporation, which in some cases can be quite significant, and also to maintain some counter-pressure, 150-200 liters of air per minute is supplied to the pneumocostume. Investigations conducted of the physiological functions have shown that a quite comfortable microclimate is created in this costume enabling

34M. 1845

LETAVET, A.A.

prolonged operation in a contaminated atmosphere without disturbing the comfort of the worker. For protection of the organs of respiration from radioactive aerosols, respirators to be used once with a highly effective filtering material are most comfortable. The usual respirators are not very suitable because of the impossibility of cleansing them of radioactive contamination.

The problem of cleaning the hands and the surface of the body of radioactive contamination has not yet been practically solved. All the substances tried for this purpose are unsatisfactory, especially when a significant period has elapsed from the moment of contamination until cleansing. Consequently, the work should be done by methods which completely eliminate contamination of the surface of the skin.

Thus, in the field of individual protection and in the field of personal hygiene, a large program of work lies ahead, both for seeking new materials and for creating more suitable and hygienic structures.

54M-1345

LETAVET, A.A.

Up to the present there has been no completely satisfactory, in a sanitary sense, and sufficiently economical method for the decontamination of fluid and solid waste materials. Therefore, in this field there lies ahead a broad program for the complex work of hygienists, hydrologists, physical chemists, and engineers. Among the methods for purification of waste waters of low radioactivity, proposed by various authors, may be mentioned a reliable but very expensive method for repeated distillation and a method of filtration by various filters having a high adsorptive capacity. For large cities having a large number of establishments using radioactive isotopes, it appears to be expedient to organize city stations for decontamination utilizing special means of transport, a system of exchange containers, etc.

At atom power plants, problems of the prophylaxis of contamination of the atmosphere by minute quantities of radioactive gaseous products, chiefly in the form of the radioactive noble gases argon and krypton, formed in the reactor through the action of neutrons, and also of radioactive aerosols must be solved.

The chronic forms of radiation sickness up to the present have not been thoroughly described and the material that is available is quite contradictory. In connection with this the periodical medical examinations of all workers using ionizing radiation is of great importance. Only by means of these periodic medical examinations is it possible to discover the initial stages of chronic radiation sickness, since the patients seldom complain and subjectively feel well. (U)

"Problems of oil and gas content in mesozoic deposits in the south
of the USSR"

Abstract. The authors discuss the principal features of tectonics in the South USSR. The general review is presented of the oil and gas distribution all over the Mesozoic sequence along with the short characterization of the reservoirs. Zones of oil and gas accumulation as well, as the single fields are described. Oil and gas possibilities in the Mesozoic rocks within the regions of the South USSR are briefly outlined.

report to be submitted for the 6th world petroleum congress, Frankfurt, West Germany, 19-26 June 1963.

SOV/20-125-4-49/74

TITLE:

On the Transition Complex of Ciscaucasia (O perakhodnom komplekse Predkavkaz'ya)

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 125, Nr 4, pp 862-865 (USSR)

ABSTRACT:

The lower tectonic level - the fundament - consisting of dislocated and metamorphized Paleozoic rock, lying under the plate complex was uncovered in Ciscaucasia by boring. In the most recent time a new red complex was uncovered which neither belongs to the fundamental rock nor to the plate envelope. This was the case in the eastern, central and western part of Ciscaucasia. Lithologically this complex is rather monotonous, with red sandy-loamy rocks on several places which partly go over into conglomerates. The grains are badly distributed. As a rule the rock is massive and structureless. Only in individual cores strata were found with an inclination of 15-45°. The stratification is quite likely to be due to both tectonic reasons and sloping structure of the strata. These recently discovered rocks are considered as sediments of a tectonic transition complex. Already several research workers (Refs 2, 3, 8, 9) had uncovered this

Card 1/3

On the Transition Complex of Ciscaucasia

SOV/20-125-4-49/74

complex in the regions bordering to the Epihercynian plate. The thickness of the uncovered complex was between 10 and 80 m. The mentioned complex lies in a sharp angular discordance on fundamental rocks of the Lower Carboniferous time (western Ciscaucasia) up to the Upper Carboniferous time (eastern Ciscaucasia) differing with respect to age and composition; they are covered by plate sediments of the Lower Jurassic (East) up to Lower Cretaceous (West) that are normal with respect to their age. With more or less great probability this complex may be regarded as belonging to the Permian-Trias. There is a close relation between its distribution and the erosion-tectonic relief of the fundament. (Fig 2). This distribution gives evidence of a very early formation of at least several plate structures in Ciscaucasia, i.e. of a formation that had already taken place before the beginning of a general downwarping and sedimentation of the enveloping rock. Conclusions from analogy are drawn with other regions. The uncovering of the complex confirms the certain existence of an Epihercynian plate. Thus, it is necessary to revise the theories set up by several scientists (Refs 1, 6) as to the early Mesozoic age of the fundament of a great part of Ciscaucasia. The limit with respect to time between the Hercynian and the Mesozoic

Card 2/3

On the Transition Complex of Ciscaucasia

SOV/20-125-4-49/74

age was in this region marked by a general elevation on the background of which plate structures began to form. It is quite likely that "breccia movements" (glybovyte dvizheniya Pl.) had taken place in this region. Thus, fosse-like depressions developed which are very characteristic of the stage of transition within the region of the Epihercynian plates (Refs 5, 8). There are 2 figures and 9 Soviet references.

TITLE:

On the Geological Development of Ciscaucasia and the Southern
Borderline of the Russian Platform (O geologicheskoy razviti
Predkavkaz'ya i yuzhnoy okrainy Russkoy platformy)

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 125, Nr 6, pp 1319-1323
(USSR)

ABSTRACT:

By means of drilling work in the region mentioned in the title
it was found (Refs 3,6) that a Predkavkazskaya (Ciscaucasian)
Epihercynian platform is developed in the south of the European
USSR. It has a younger folded basis than the Prepaleozoic
Russian platform. The boundary between these two platforms runs
along a line of faults which form the northern boundary of the
folds of the Donbass (Donets basin). The eastern boundary is
not so distinctly marked (Refs 2,8). The authors compiled a
scheme of the predominating development of stratigraphic com-
plexes of the Paleozoic and a map of the transgressive super-
impositions of the Neozoic complex. By putting
one map over the other (Fig 1) it was possible to draw several
conclusions and to indicate the dependence of the depressions

of the Mesozoic on tectonic tendencies of the Hercynian cycle. The authors drew the following conclusions from the results obtained by the application of the two afore-mentioned methods: Submeridional waves of fluctuations were very important in the course of the Hercynian and Mesozoic. The main traits of the Hercynian structure influenced to a certain extent the development at the beginning of the Mesozoic: the regions of eastern Ciscaucasia which were depressed to the greatest extent at the end of the Paleozoic were earlier involved into the depression. They were subjected to a transgression already during the Jurassic. The regions of western Ciscaucasia, which attained the highest altitude at the end of the Paleozoic, were subjected to the transgression as late as at the end of the Lower and at the beginning of the Upper Cretaceous. Ciscaucasia as well as the adjacent southern part of the Russian platform were subjected to these meridional large depressions. These data confirmed the known hypothesis of N. S. Shatskiy (Ref 7) that an anticaucaasian gigantic structure existed in Ciscaucasia and in the south of the Russian platform which contained various tectonic zones. Its Paleozoic origin as well as the perpetua-

tion of the main rules governing the tectonic development of
the Hercynian cycle in the Mesocenozoic were confirmed.

TITLE:

Main Features of the Mesocenozoic Development of the South of
the European Part of the USSR

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 127, Nr 5,
pp 1089 - 1091 (USSR)

ABSTRACT:

The authors analyzed the distribution of the thickness of large stratigraphic complexes in the area mentioned in the title which correspond to the main stages of the geotectonic development of this vast area. The purpose was to determine the rules governing the development in Mesocenozoic. The following stages were identified: a) Lower Jurassic, b) Upper Jurassic, c) Lower Cretaceous, d) Upper Cretaceous, e) Paleocene-Eocene, Oligocene - Lower Miocene (Maykop), Middle Miocene - Middle Pliocene and Upper Pliocene - Quaternary. For the purpose of determining paleostructural interrelations schematic maps were compiled. The following conclusions may be drawn from the results: 1) After a general elevation towards the end of Paleozoic the mentioned area was subjected to sheet-like depressions

Card 1/3

Main Features of the Mesozoic Development of the
South of the European Part of the USSR

SOV/26-127-5-43/58

beginning with the Jurassic. In each stage until the Upper Cretaceous (Ref 6) always new sheets were included. The sequence of transgression and regression which followed the former was complicated as was found already in 1994 by A. P. Karpinakiy (Ref 5). 2) This gradual development took place in Mesozoic beginning in the East and in the South. 3) The waves of the depressions are the total background of the fluctuations which was rendered complicated by the development (of the Hercynian stage) of genetic structures in the range of the Epihercynian platform. 4) The tectonic differentiation by Pred-Kavkaz'ye (Cis-Caucasia) on the one hand, and of the southern edge of the Russian Platform on the other, differed in Mesozoic: in the range of the pre-Paleozoic platform the structures of the I and the II order developed which are still slightly expressed in the Paleozoic, whereas the sheet-like structural elements in the area of the Epihercynian platform were only at the beginning of their formation at that time. 5) The alpine pre-downwarplings to which earlier the entire area of Cis-Caucasia to the Marysk valley was counted (Ref 1) occupy relatively small local sections (Refs 3,4,9) and are separated into 2 basins: a) Kuban-

Card 2/3

Main Features of the Mesozoic Development of the
South of the European Part of the USSR

SC7, 20-127-5-33/58

Indol'skaya and b) Tersko-Kaspiyskaya. The Belomechetskiy (East Kuban') downwarping may not be counted to the pre-downwarpings. It is a pure sheet-like formation i.e. part of the Central Kuban' depression. The formation of the pre-downwarpings a) and b) began in the Oligocene and was especially intense in the Middle and Upper Miocene; it still continues. 6) In the Mesozoic history of Cis-Caucasia a combination of (in a larger sense) genetic development and the formation of newly formed structure may be observed. There are 10 Soviet references.

TITLE The Use of Periodically Recurrent Rolled Sections at the Gor'kiy Auto Plant im. Molotov (O primeneni periodicheskikh profiley prokata na Gor'kovskom avtozavode im. Molotova)

PERIODICAL V sb. Ratsionalizatsiya profiley prokata. Moscow, Profizdat, 1956. pp 337-338

ABSTRACT Much metal has been saved at this plant by the use of periodically recurrent rolled sections for the front axles of the GAZ-51 truck and for the crankshaft of the M-20. Realization of this plant's proposals for the production by helical rolling of parts consisting of bodies of revolution would make it possible to save ~ 2,000 t of rolled metal per year.

TITLE: Properties of Steel 20XCP. (Svoystva stali 20XCP).

PERIODICAL: "Stal'" (Steel), 1957, No.6, p.564 (USSR).

ABSTRACT: The Gorkovskiy Automobile Works together with the Automobile Scientific-Research Institute and Zlatoustovskiy Metallurgical Works developed a new low alloy structural steel 20 XCP which is used instead of steel 20 XHM. The composition of the steel %: C 0.17-0.24; Si 0.17-0.37; Mn 0.7-1.0; S < 0.04; P < 0.04; Cr 0.8-1.1; Ni < 0.3; B 0.002-0.005. Although titanium is not included in the specified composition, the deoxidation of this steel with titanium is necessary before the addition of ferroboron. The steel is produced on the Zlatoustvskiy Works and delivered to motor car works in the form of hot rolled products from which automobile parts are stamped under normal conditions (1250-1300 C) without any difficulties. After normalisation from 870-900 C parts are easily machined even without annealing. Cementation in gaseous or solid medium of this steel is more intensive than that of steel 20 XHM which speeds up the process by 10-12%. Automobile parts from this steel were tested under laboratory

Card 1/2

Properties of Steel 20X1P. (Cont.)

TITLE: Application of Converter Steel in the Automobile
Industry

PERIODICAL: Metallovedeniye i termicheskaya obrabotka metallov,
1960, No.11, p.46.

TEXT: Data are given on industrial tests relating to the
use of converter steel (0.17% C, 0.46% Mn, 0.032% S, 0.038% P) in
the motor car industry. From 8 ton ingots of three commercial
melts, strip was rolled which was used for producing rims of truck
wheels. It was found that the chemical composition and the
mechanical properties are the same as for open hearth steel. At
the Gor'kiy Automobile Works 2900 such rims were produced and the
performance of 1684 of them was closely observed. The number of
rejects due to cracking along the weld seam during stretching of the
rim was 0.87% for the experimental batch as compared to 0.71% for
the batch made of open hearth steel of a similar composition. With
these rims disc wheels were made which were fitted on 264 trucks.

Application of Converter Steel in the Automobile Industry

So far, these trucks have run over 50 000 km. It is concluded from the results that the investigated converter steel is as good as open hearth steel, particularly for hot rolled and cold rolled sheets which are to be used for deep drawing. There is 1 table.

TITLE: Chrome-manganese-nickel steel with nitrogen for internal combustion exhaust valves

SOURCE: Avtomobil'naya promyshlennost', no. 3, 1966, 31-33

TOPIC TAGS: internal combustion engine, valve, high temperature steel, chromium, manganese, nickel, hardness, durability, engine reliability, CHROMIUM STEEL, MANGANESE STEEL, NICKEL STEEL / EP303 HIGH TEMPERATURE STEEL

ABSTRACT: The authors discuss and criticize various grades of steel used for valve production. A comparison of existing grades of steel for valve production shows that EP303 steel is best suited for this purpose. It retains its hardness at temperatures of 700-900°C. This shows that it can withstand temperatures from 50 to 100 degrees higher than EI69 and EP48 steels. EP303 steel was tested for thermal stability to determine its resistance to scale formation in air and corrosion resistance in lead oxide at 900°C. EP303 steel compares favorably with the other grades of steel tested. The test results were used as a basis for trying out this steel in the mass production of valves. The manufacturing process is discussed. Valves made from EP303 and EP48

steels were then compared on ⁴test stands and under operating conditions. These tests were carried out at the Gor'kiy Automobile Plant. The valves were tested in GAZ-51, GAZ-51a and GAZ-21d engines and others. High octane gasoline was used throughout the test since it develops high temperature conditions. Tests showed that valves made from EP303 steel retain their clearances throughout the test period in contrast to those made from EP48 steel. The data acquired during stand testing are in agreement with operational data. Valves made from EP303 steel have a hardness of HRC 38. These valves operate very well in GAZ engines and improve engine reliability. The service life of the new valves is triple that of valves with a built up VKhN-1 facing, and more than four times that of valves made from EP48 steel. The production of EP303 steel has been adopted by the Gor'kiy Automobile Plant for making the exhaust valves of GAZ and ZMZ engines. Orig. art. has: 4 figures, 1 table. 2
